Reinforcement learning and robot navigation

Introduction

The problem

- Framework: a raspberry pie 3 robot which can follow lines
- The task: the robot should adapt its speed with respect to traffic lights
- How: using Reinforcement Learning (RL) and Markov Decision Process (MDP)

The task

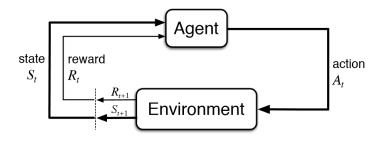

Presentation

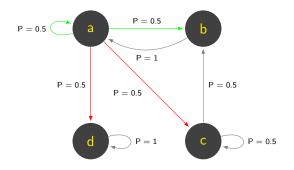

- Part I: theoretical insight
- Part II: results from first implementations

Reinforcement learning

The agent's job is to find a behavior that maximizes the long-run sum of values of the rewards.

Markov Decision Process intuition

actions possible in state 0:

 $lue{1}$ ightarrow: action 1

 \bigcirc \rightarrow : action 2

Episode : s_0 ; a_1, s_1, r_1 ; a_2, s_2, r_2 ; ...; a_n, s_n, r_n

Markov Decision Process

Definition: (MDP)

- A set of states $S = \{s_0, s_1, s_2, \dots, s_n\}$
- A set of actions $A = \{a_1, a_2, a_3, \dots, a_k\}$
- A transition function $T(a, s, s') = \mathbb{P}[s' \mid a, s]$
- A reward function $R: \mathcal{S} \mapsto \mathbb{R}$
- A discount factor $0 \le \gamma < 1$

Markov property

The transitions only depends on the current state and the current action.

How to pick actions

Definition: (policy)

A *policy* π is a probabilistic mapping from the set of states to the set of actions :

$$\pi: \mathcal{A} \mathcal{X} \mathcal{S} \mapsto [0,1]$$

s.t.
$$\sum_{a} \pi(a \mid s) = 1 \quad \forall s \in \mathcal{S}$$

Issue

How to

How to asses the quality of policies so we can find the best one? What is the best policy?

We are interested in maximizing the discounted return: G_t

$$G_t = \sum_{k=0}^{\infty} \gamma^k R_{t+k+1} = R_{t+1} + \gamma G_{t+1}$$

We are interested in maximizing the discounted return: G_t

$$G_t = \sum_{k=0}^{\infty} \gamma^k R_{t+k+1} = R_{t+1} + \gamma G_{t+1}$$

Action value while in a state s under π

$$q_{\pi}(s, a) = \mathbb{E}_{\pi}[G_t \mid S_t = s, A_t = a]$$

We are interested in maximizing the discounted return: G_t

$$G_t = \sum_{k=0}^{\infty} \gamma^k R_{t+k+1} = R_{t+1} + \gamma G_{t+1}$$

Action value while in a state s under π

$$q_{\pi}(s,a) = \mathbb{E}_{\pi}[G_t \mid S_t = s, A_t = a]$$

State value under policy π

$$v_{\pi}(s) = \mathbb{E}_{\pi}[G_t \mid S_t = s]$$

Recursive definition of value functions

action value

$$q_{\pi}(s, a) = \sum_{s'} \mathbb{P}(s' \mid a, s) \left[R(s') + \gamma v_{\pi}(s') \right]$$

state value

$$v_{\pi}(s) = \sum_{a} \pi(a \mid s) \sum_{s'} \mathbb{P}(s' \mid a, s) \left[R(s') + \gamma v_{\pi}(s') \right]$$

How to compare two policies

$$\pi \leq \pi' \iff v_{\pi}(s) \leq v_{\pi'}(s) \quad \forall s \in \mathcal{S}$$

How to compare two policies

$$\pi \leq \pi' \iff v_{\pi}(s) \leq v_{\pi'}(s) \quad \forall s \in \mathcal{S}$$

Optimal policy

$$\pi_*$$
 s.t. $\forall \pi : \pi_* > \pi$

Bellman optimality equations

We can associate the value function v_* and q_* to the optimal policy π_*

$$v_*(s) = \max_a \, q_*(s,a)$$

$$q_*(s, a) = \sum_{s'} \mathbb{P}(s' \mid s, a)[R(s') + \gamma \max_{a'} q_*(s', a')]$$

Finding optimal policy from value functions

$$\pi_*(s) = \underset{a}{\operatorname{argmax}} \ q_*(s, a)$$

Another issue

Computational issue

- $\mid \mathcal{S} \mid$ linear equations to solve to evaluate policy
- $\mathcal{S} \mid$ non linear equations to solve the Bellman optimality equation

Another issue

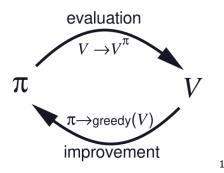

Computational issue

- $\mid \mathcal{S} \mid$ linear equations to solve to evaluate policy
- $\mathcal{S} \mid$ non linear equations to solve the Bellman optimality equation

Approximation of value function and Policy iteration

Policy iteration algorithm

solving MDP using dynamic programming

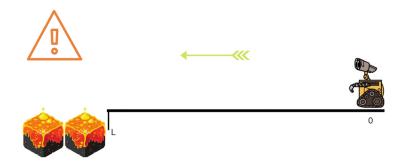

¹From (Sutton & Barto, 1998)

Our problem

First a simpler problem

Modelization

states

- position {0,1,2,...,L, Lava }
- ullet speed $\{ \mbox{low, medium, high } \}$

Modelization

states

- position {0,1,2,...,L, Lava }
- speed {low, medium, high }

actions

- decelerating
- maintaining speed
- accelerating

Modelization

states

- position {0,1,2,...,L, Lava }
- speed {low, medium, high }

actions

- decelerating
- maintaining speed
- accelerating

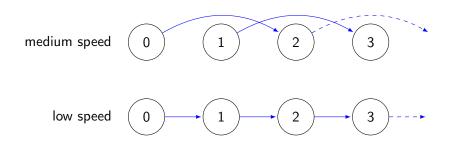

reward function

- Lava: reward of -L
- L in low speed: reward of +L
- any other state : reward of -1

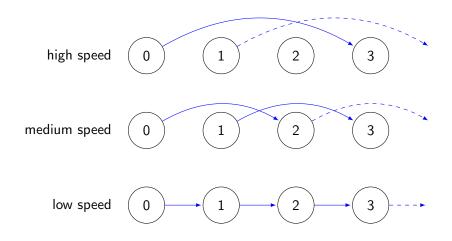

Action of keeping the same speed graph

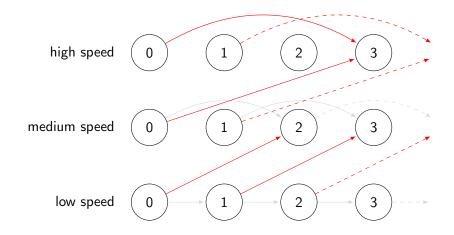

Action of keeping the same speed graph

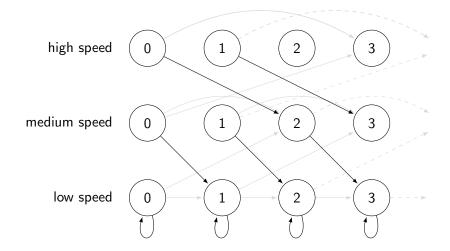

Action of keeping the same speed graph

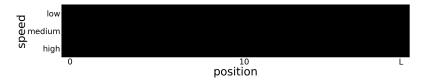

Action of accelerating

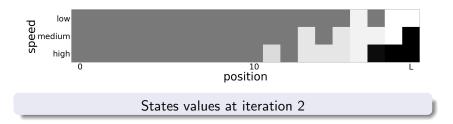

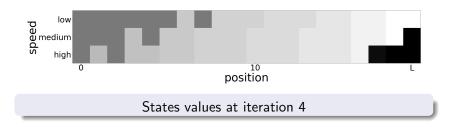

Decelerating

States values at iteration 0, all the state values are equal to 0

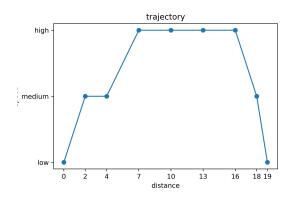

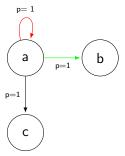

States values at iteration 6 (where stable policy is attained)

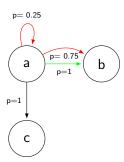

Results for deterministic actions One of the optimal trajectories

Deterministic actions are not really realistic

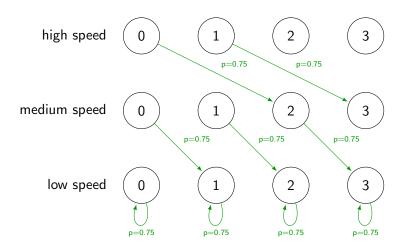

Deterministic actions

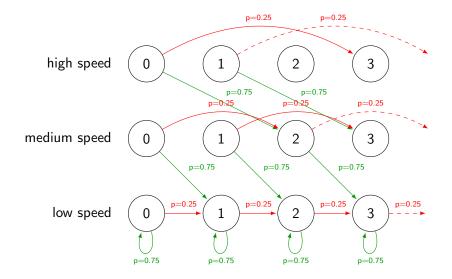

Stochastic actions

Decelerating for decelerating being a stochastic action

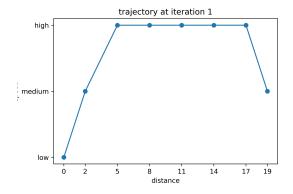

Decelerating for decelerating being a stochastic action

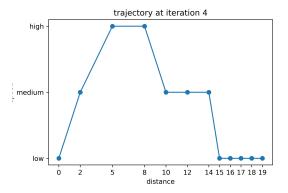

Results for stochastic actions

decelerating results in keeping the same speed with probability 1/4

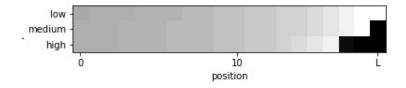

Results for stochastic actions

decelerating results results in keeping the same speed with probability 1/4

where stable policy is attained

Results for stochastic actions state-value function at the end of the iterations

Conclusion

- We introduced the theoretical framework: Reinforcement learning and Markov Decision Processes
- We solved a simple problem where we know the model (the transition function in particular)

What's next?

already working on

- Add the traffic light into this setting
- Find the distance from the robot's camera to the traffic light
- getting data from the robot

In a not so distant future

- Explore other algorithms and compare them: Monte-Carlo methods, temporal difference learning, Q learning, Expected Sarsa...
- Neuro-dynamic programming ?

What's next?
